Quantum Chromodynamics – QCD

* what? theory of strong interactions: quarks & gluons

  ↳ non-Abelian gauge theory $SU(N_c)$

  ($N_c = 3$; colour d.o.f)

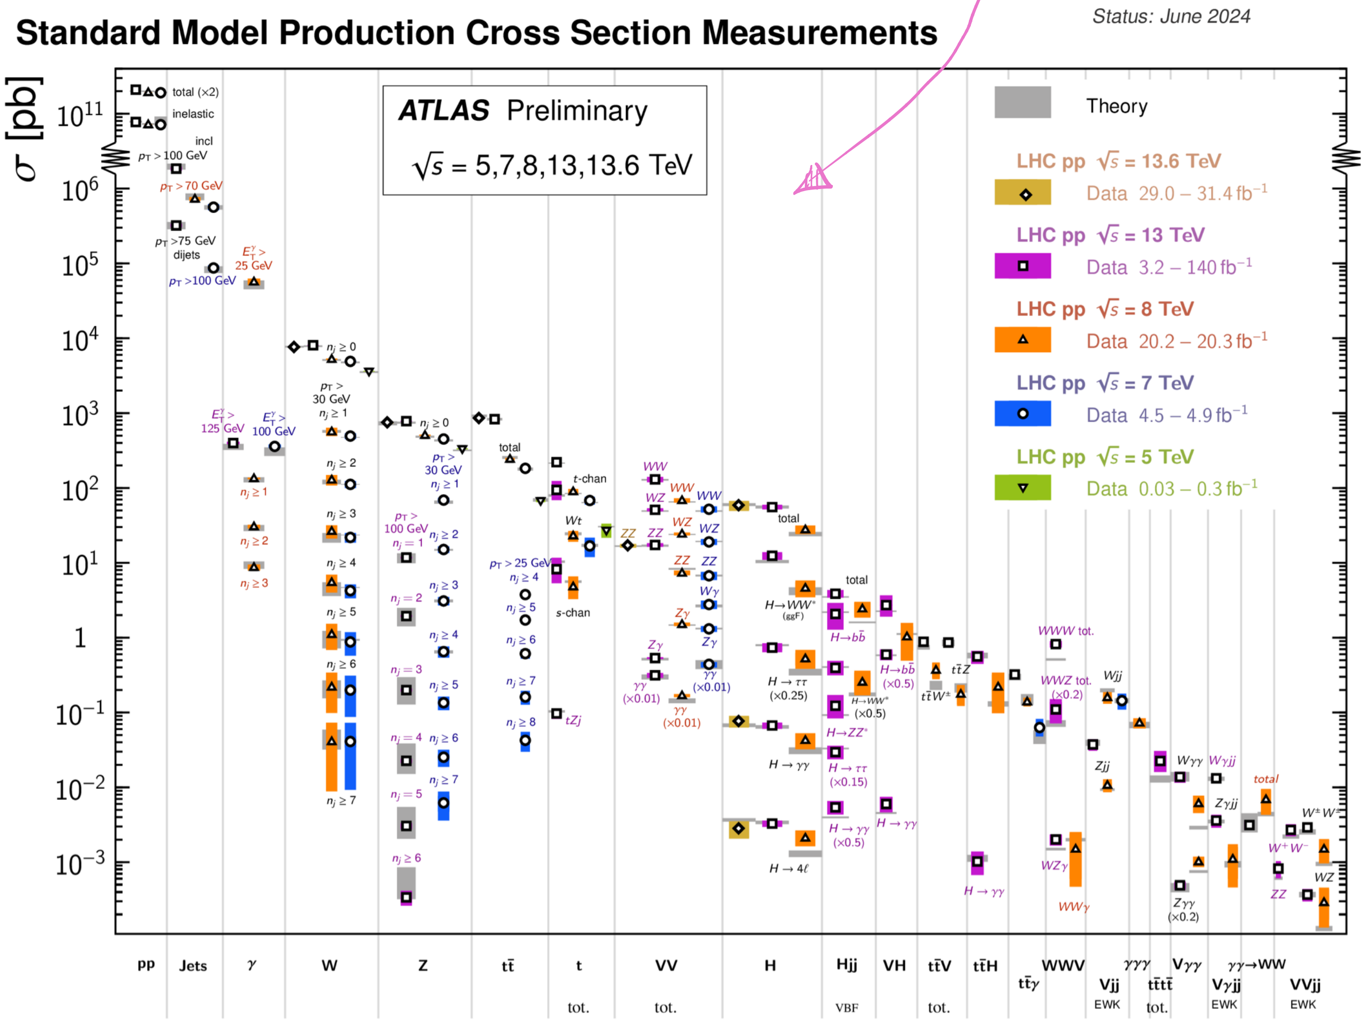
* why? unavoidable in hadron collisions

  (LHC collides protons ≃ QCD bound states)

① measure properties & scrutenize the KNOWN

② enhance the discovery reach of the UNKNOWN

"stairway to heaven" plot



> Quantum chromodynamics is conceptually simple.

Frank Wilczek

$$\mathcal{L}_{QCD} = \sum_q \bar{\psi}_q (i \gamma^\mu D_\mu - m_q) \psi_q - \frac{1}{4} F^a_{\mu\nu} F^{a,\mu\nu}$$

with

$$D_\mu = \partial_\mu + i g_s A^a_\mu t^a \quad \text{and} \quad F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu - g_s f^{abc} A^b_\mu A^c_\nu$$

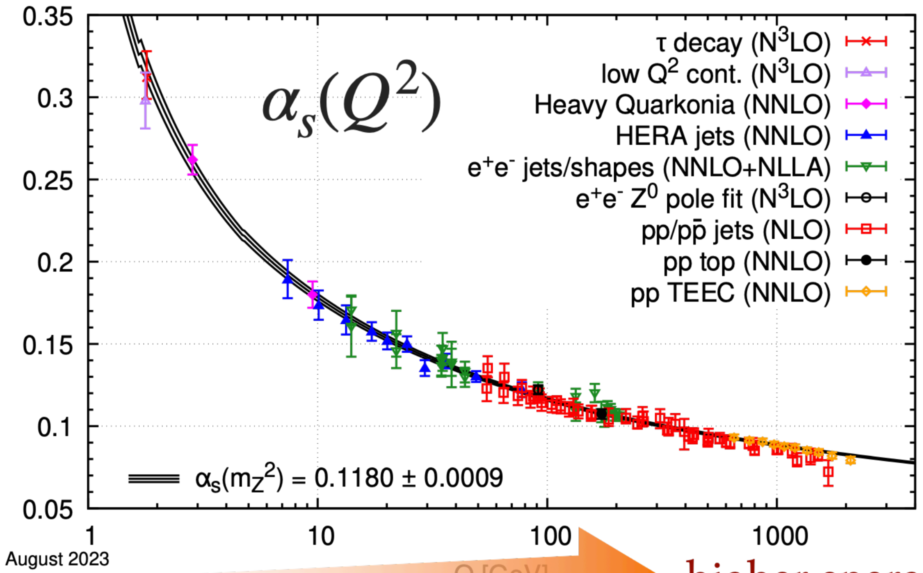
that's it!

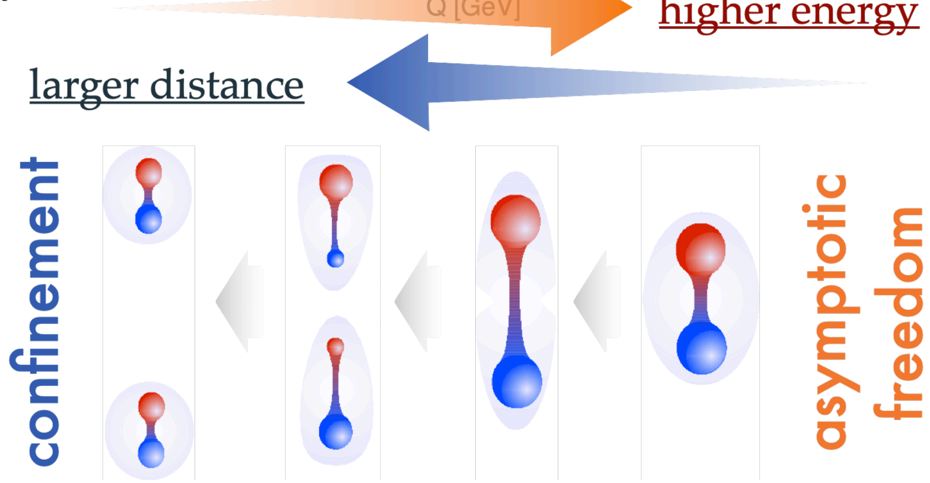
> Quantum chromodynamics is conceptually simple. Its realization in nature, however, is usually very complex.

Frank Wilczek

strong interaction ↭

- Quantum Chromodynamics (QCD)



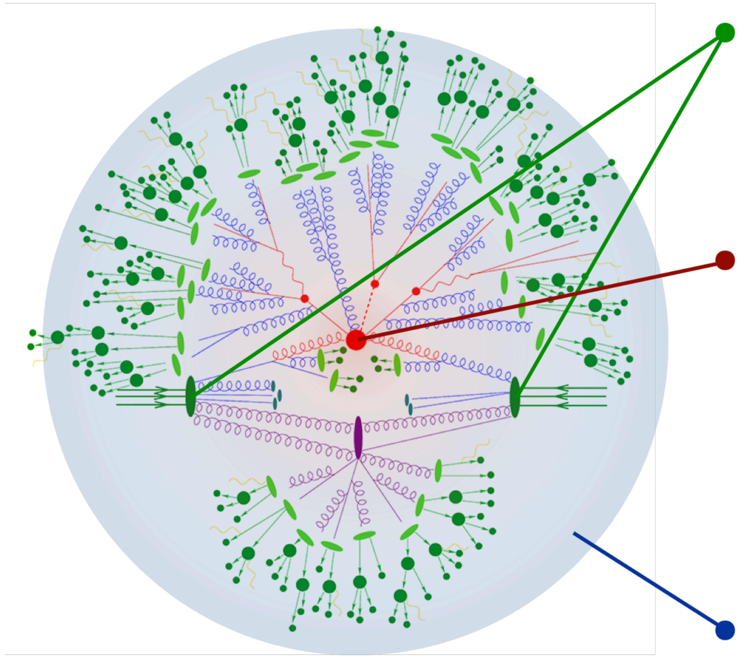


* no free quarks & gluons
→ spray of hadrons ($\pi^\pm, K^\pm, K^0, p^\pm, n, \ldots$)

* colliding objects (p @ LHC) not elementary

> Quantum chromodynamics is conceptually simple. Its realization in nature, however, is usually very complex. But not always.

Frank Wilczek



incoming protons

- quarks & gluons

short distance "hard"

- high scales: 10^2–10^3 GeV

evolution towards a physical observable state

long distance "soft"

- low scales: $\mathcal{O}$(few GeV)

① factorization

↪ relevant physics at disparate scales (isolates description of proton from rest)

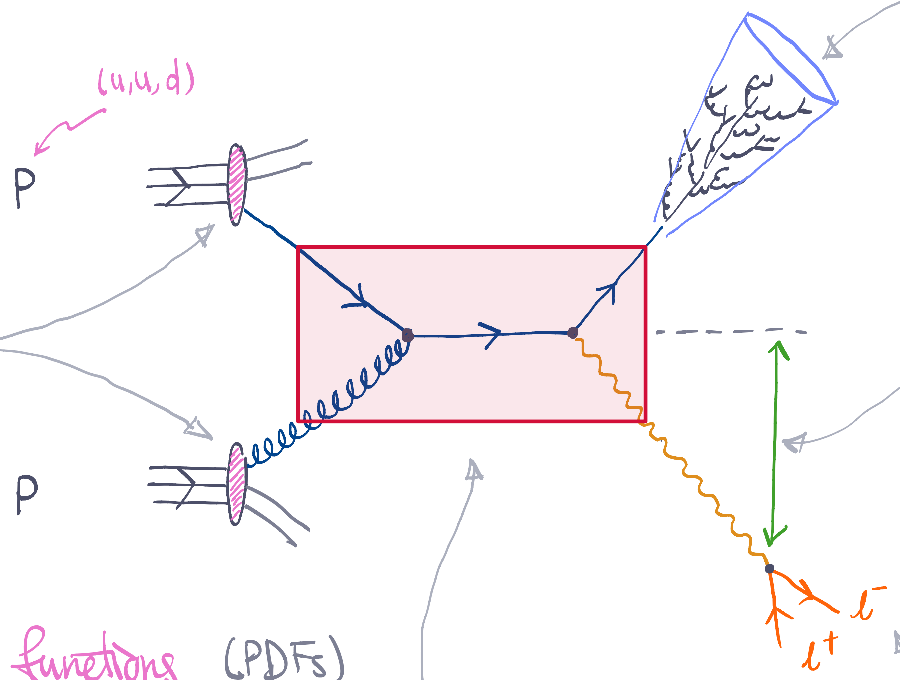
② asymptotic freedom

↪ short distance ⟷ perturbation theory

$$\sigma = \sigma_{LO}\left(1 + \alpha_s\, c^{(1)} + \alpha_s^2\, c^{(2)} + \ldots\right)$$

Goal of these lectures

* understand, how this picture comes about
* get a feeling of how calculations are done within each part



"jet" – collimated spray of final-state hadrons

disparity of scales ($q_T \to 0$)

- resummation of large logarithms

parton distribution functions (PDFs)

- non-perturbative, but <u>universal</u>

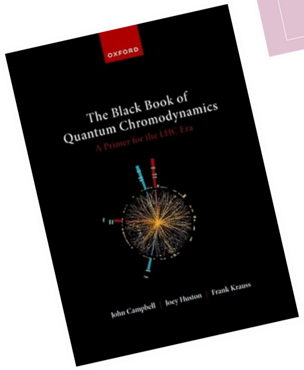
"hard" scattering

- perturbative

Z boson

- a probe

Some Literature



* Quantum Chromodynamics

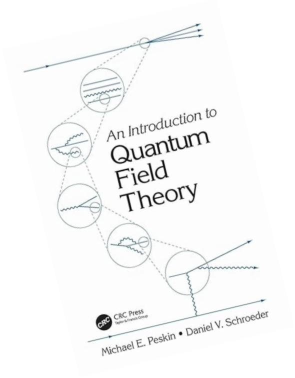
↪ Ellis, Stirling, Webber aka "The pink book"

"QCD and Collider Physics"

↪ Campbell, Huston, Krauss

"The black book of Quantum Chromodynamics"

available as free download thanks to SCOAP3 foundation



* Quantum Field Theory

↪ Peskin, Schroeder

"An Introduction to Quantum Field Theory"

Conventions & Sources

* Conventions natural units: $[\hbar] = [c] = 1$

↪ $[\text{length}] = [\text{time}] = eV^{-1}$

$[\text{mass}] = [\text{energy}] = [\text{momentum}] = eV$

↪ four vectors $x^\mu = (t, x, y, z)^T$, $\partial_\mu = (\partial_t, \vec{\nabla})^T$

⇒ energy-momentum conservation: $(a+b \to 1+2)$

$$\delta^{(4)}(p_1 + p_2 - (p_a + p_b)) = \delta(E_1 + E_2 - (E_a + E_b))\, \delta^{(3)}(\vec{p}_1 + \vec{p}_2 - (\vec{p}_a + \vec{p}_b))$$

↪ scalar product $a \cdot b = a^\mu b_\mu = a^\mu g_{\mu\nu} b^\nu = a^0 b^0 - \vec{a} \cdot \vec{b}$

$$g^{\mu\nu} = \text{diag}(+1, -1, -1, -1)$$

Outline

∅ The Beginnings

- the eightfold way
- the quark model
- colour quantum number
- confinement

I Basics of QCD

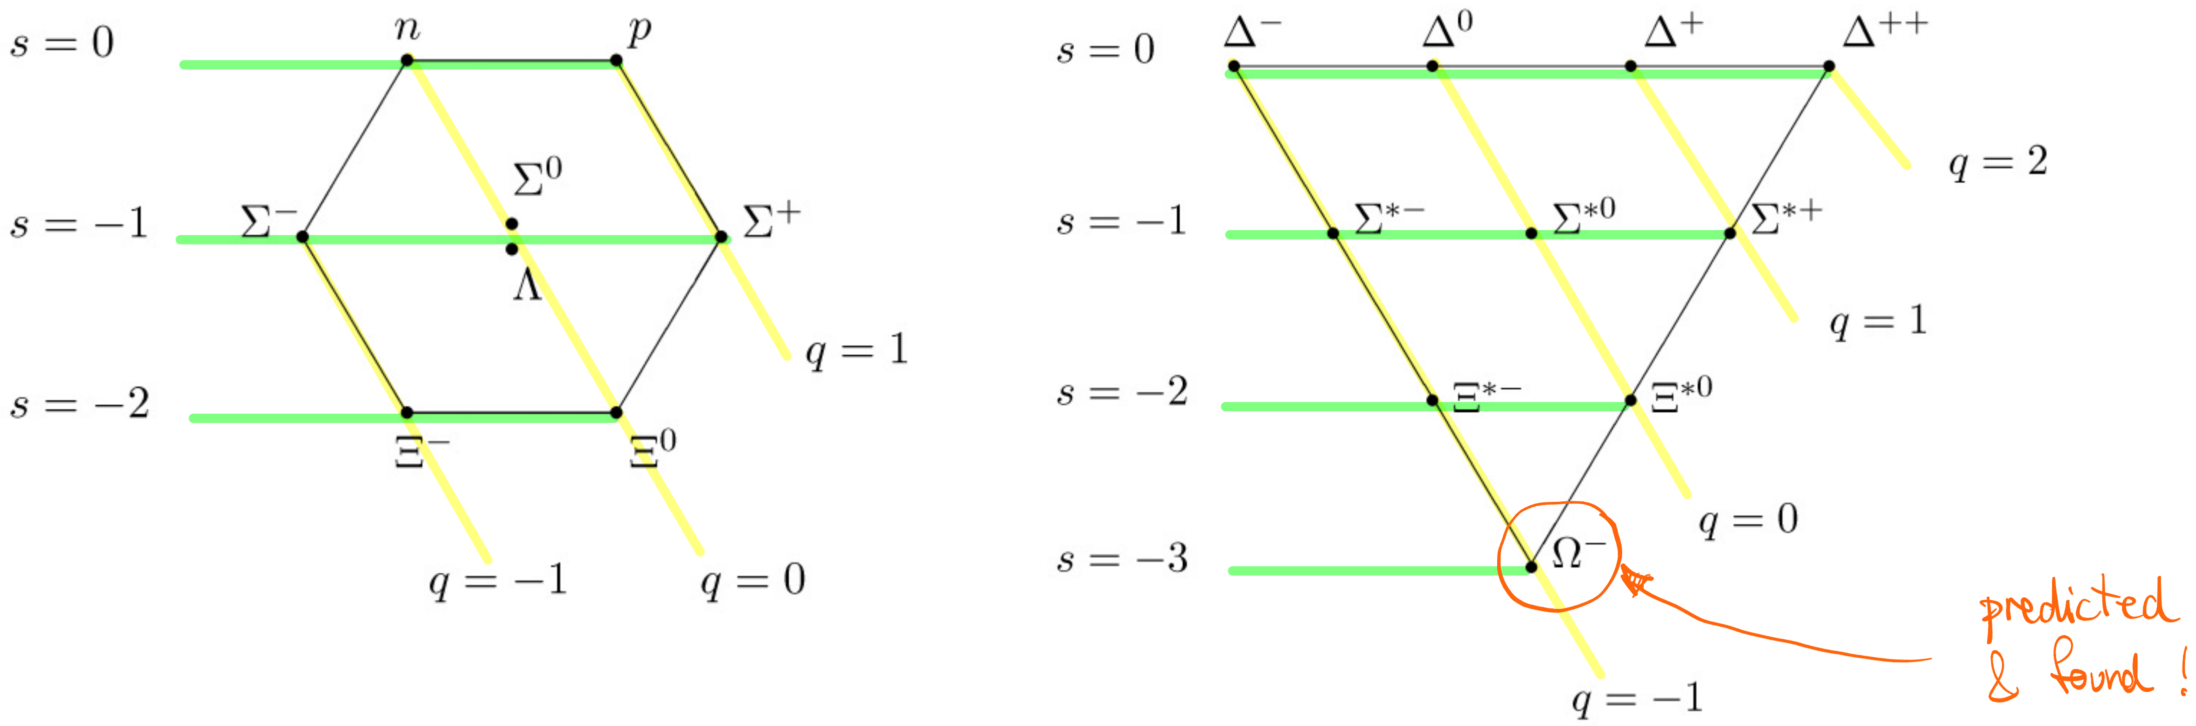
II QCD in e^+e^- Collisions

III Hadron Colliders

IV Jet Physics

The Eightfold Way [Gell-Mann '61]

* the hadron spectrum exhibits a striking pattern (s = "strangeness")



↳ What is the reason for this pattern?

The Quark Model [Gell-Mann, Zweig '64]

* proposal: spin-$\frac{1}{2}$ constituents

(quarks: $\boxed{u, d, s}$) SU(3) flavour symmetry

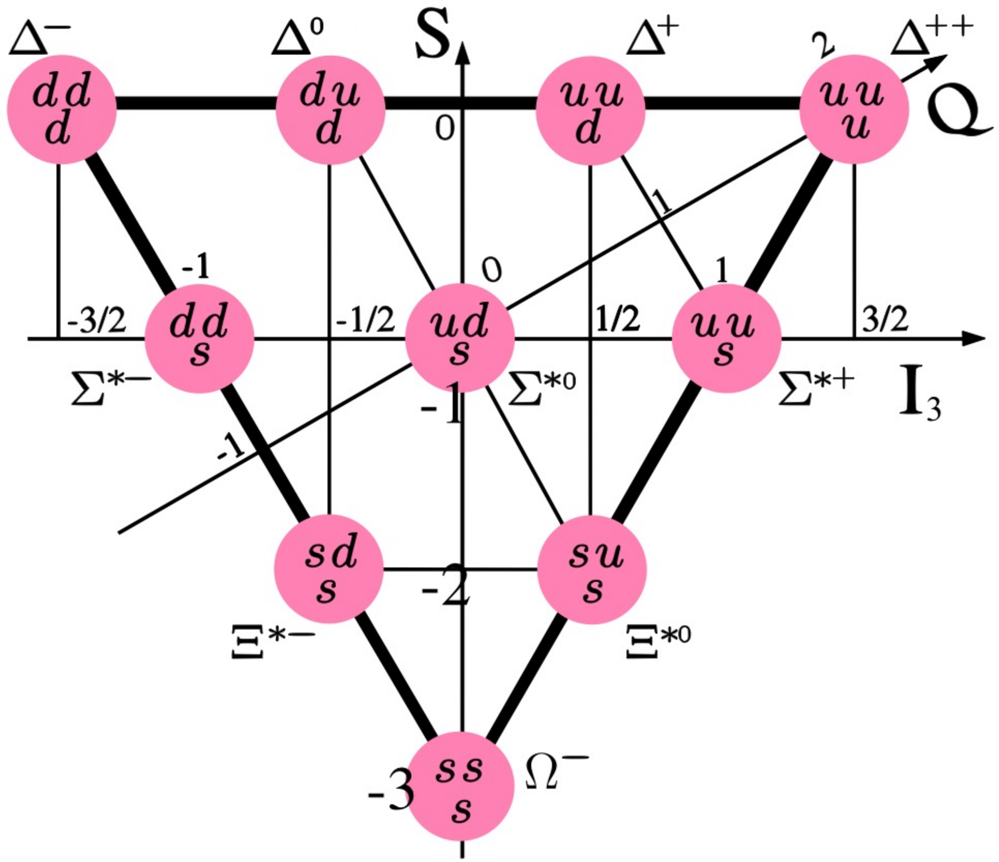
with fractal charges

u $m_u \sim 4$ MeV $(Q = +2/3)$

proton stable

d $m_d \sim 7$ MeV $(Q = -1/3)$

s $m_s \sim 135$ MeV $(Q = -1/3)$



⇒ "Explains" the pattern

but no free quarks can be seen!

The Spin-Statistics Issue

* Δ^{++} is a state with
  - spin $\frac{3}{2}$ $\quad|\uparrow\uparrow\uparrow\rangle$
  - $3\times$ up $\quad|uuu\rangle \quad (Q=+2)$

↯ Pauli's exclusion principle

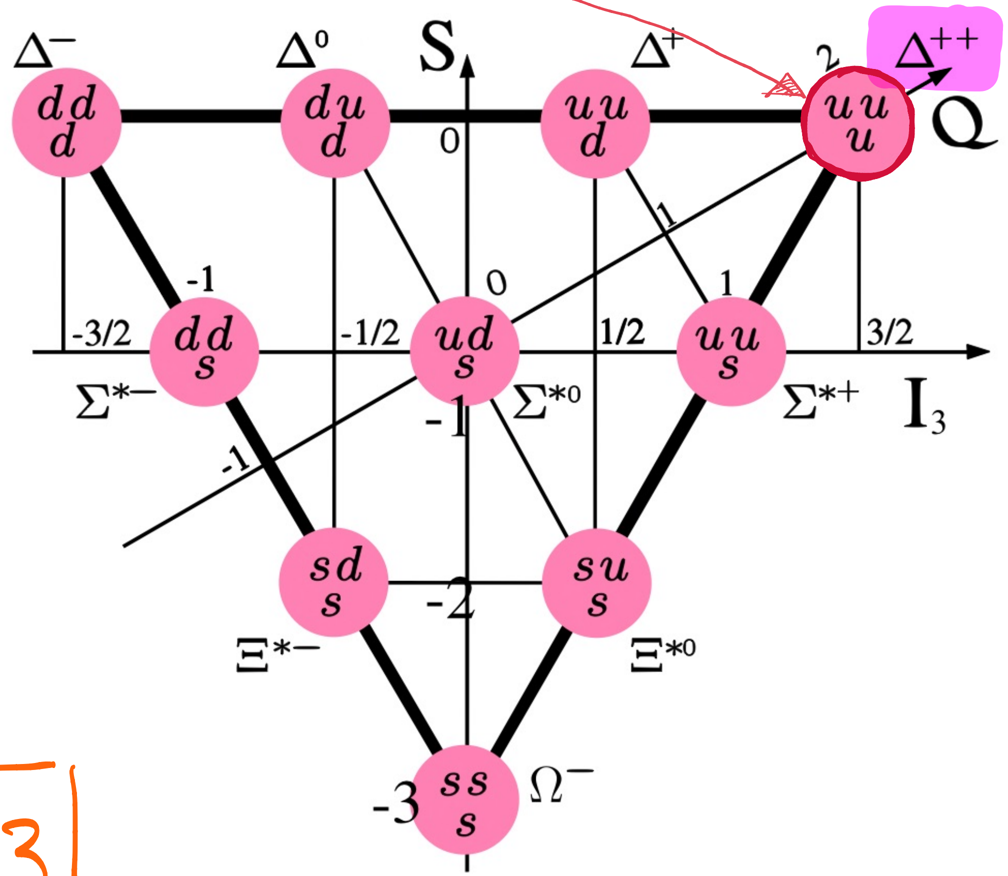
$\Rightarrow$ Way out: A new quantum number

$u^1 \quad u^2 \quad u^3 \quad ?$ } COLOUR

$\Delta^{++} \sim \epsilon^{ijk}\, u^i\, u^j\, u^k$

$\Leftrightarrow$ fully anti-symmetric

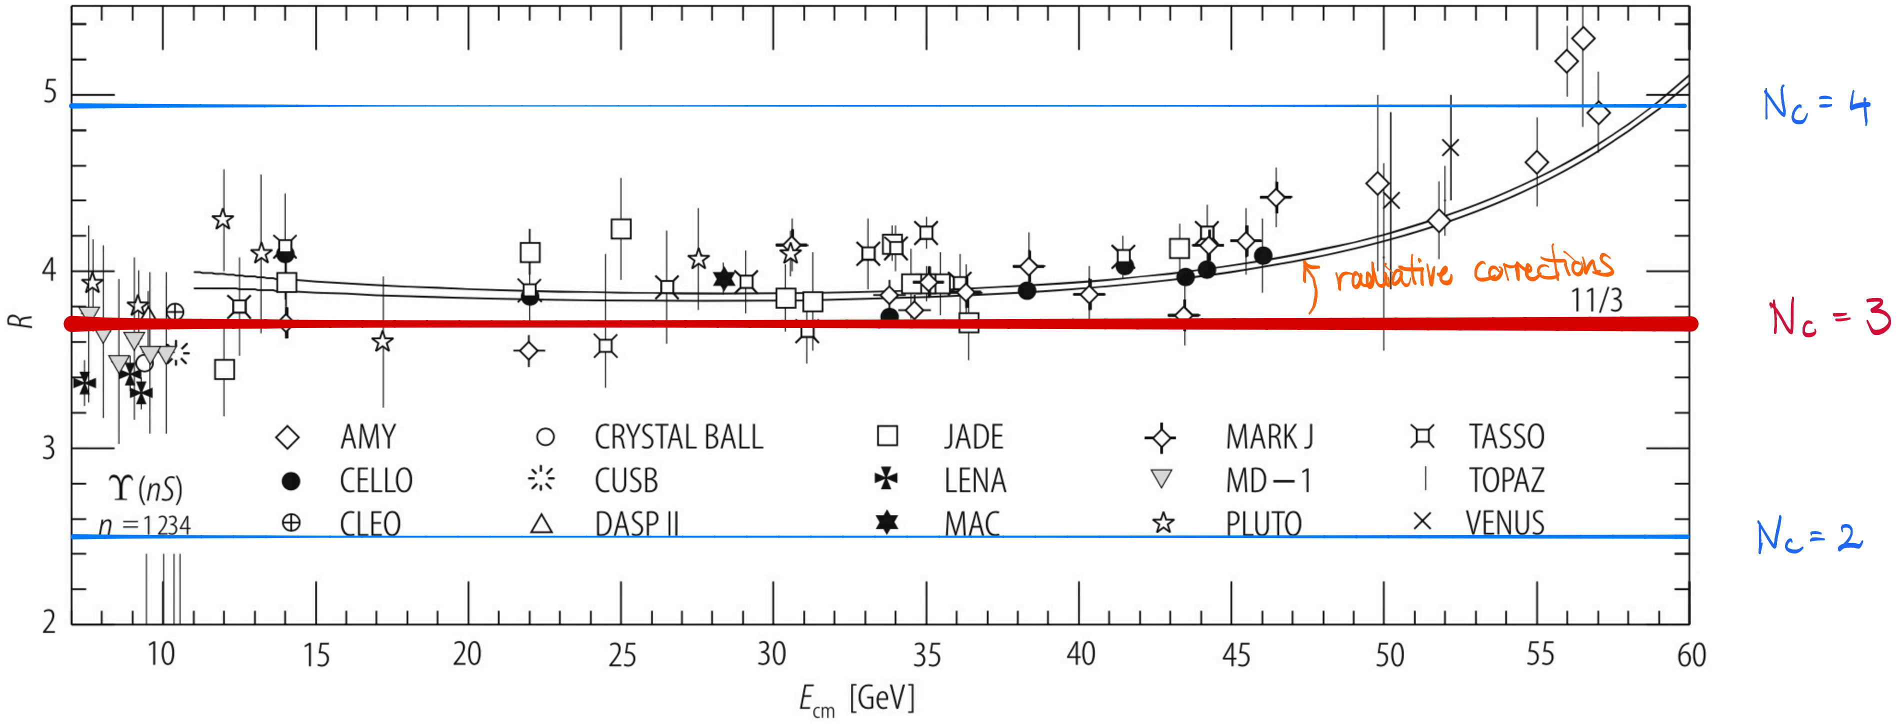
$\boxed{N_c \geq 3}$



Evidence for Colour

* The R-ratio $R \equiv \frac{\sigma(e^+e^- \to \text{hadrons})}{\sigma(e^+e^- \to \mu^+\mu^-)} \propto N_c \sum_q Q_q^2$

$\underbrace{\text{lowest-order prediction}}$ $R = N_c \frac{11}{9}$



* pion decay $\Gamma(\pi^0 \to \gamma\gamma) \propto N_c^2$
* ABJ anomaly cancellation
* much much more (BR of W, τ decays ...)

$$\boxed{N_c = 3}$$

QCD & Colour Confinement

* QCD has an exact $SU(N_c)$ symmetry why not $SO(N_c)$?

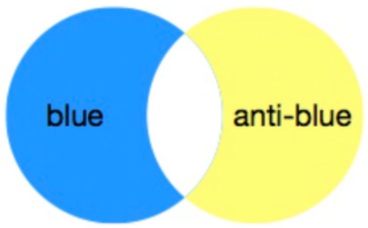
$$UU^\dagger = U^\dagger U = \mathbb{1}\,, \quad \det(U) = 1$$

* no isolated colour charges $\left(V_{q\bar q}(r) \simeq C_F \left[\frac{\alpha_s(r)}{r} + \dots + \sigma r \right] \right)$

$\Rightarrow$ only colour singlet particles $\rightsquigarrow$ hadrons have integer electric charge

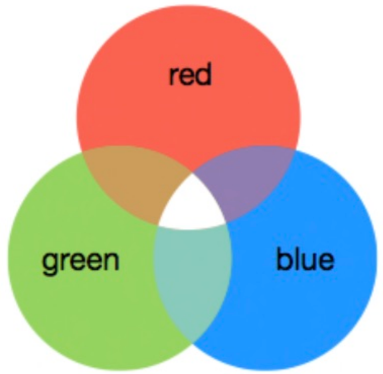
① Mesons (bosons: $\pi, \rho, \dots$)

$$\bar q^i q^i \longrightarrow \underbrace{U^*_{ij}\,\bar q^j\, U_{ik}}_{(U^\dagger)_{ji}\, U_{ik} = \delta_{jk}} q^k = \bar q^i q^i$$



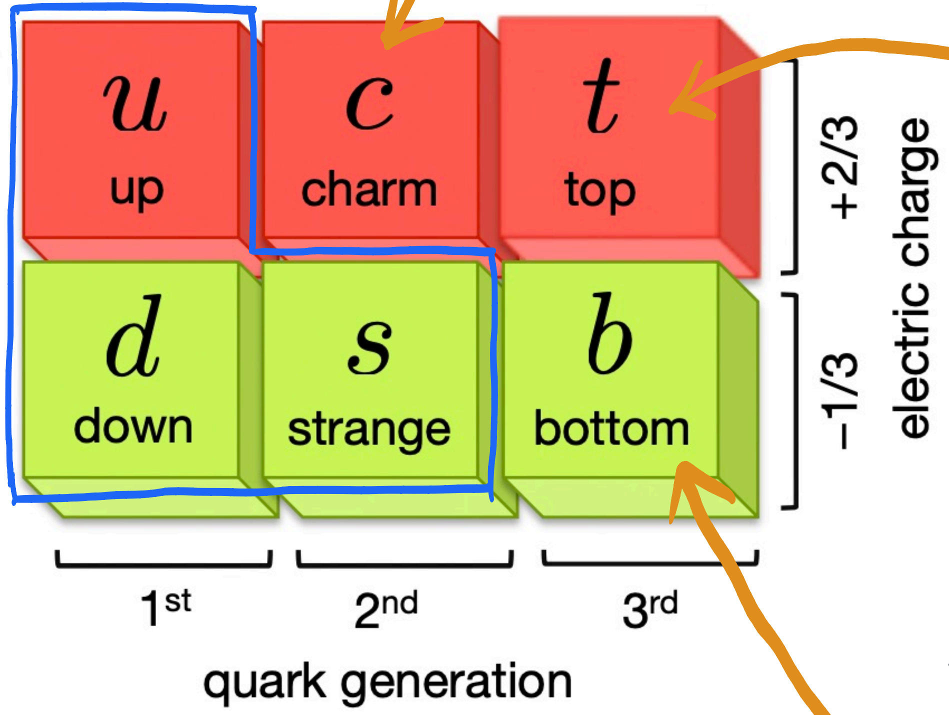
② Baryons (fermions: $p, n, \dots$)

$$\epsilon_{ijk}\, q^i q^j q^k \longrightarrow \underbrace{\epsilon_{ijk}\, U_{ii'} U_{jj'} U_{kk'}}_{\det(U)\, \epsilon_{i'j'k'}} q^{i'} q^{j'} q^{k'} = \epsilon_{ijk}\, q^i q^j q^k$$

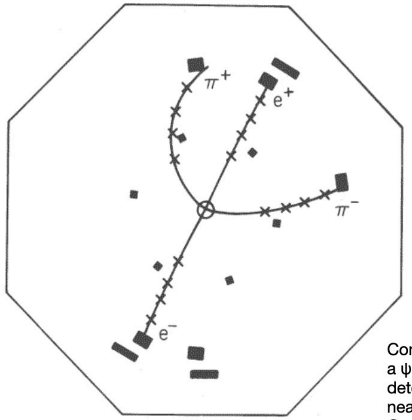


The Rest of the Family

The eightfold way



[postulated '70
GIM mechanism] → discovery '74



Computer reconstruction of a ψ′ decay in the Mark I detector at SLAC, making a near-perfect image of the Greek letter ψ

$J/\psi \hat{=} (c\bar{c})$ "charmonium"

'87 $m_t > 50$ GeV (B- oszillation)

<'94 $m_t \in [145, 185]$ GeV (EW precision)

discovery '95 $m_t = 173$ GeV

[postulated '73
CP violation
Kobayashi & Maskawa] → discovery '77 (Υ)

Outline

∅ The Beginnings

I Basics of QCD

- the QCD Lagrangian
- pQCD & Feynman rules
- the $SU(N_c)$ colour algebra
- renormalization & running coupling

II QCD in e^+e^- Collisions

III Hadron Colliders

IV Jet Physics

The QCD Lagrangian

* idea: use information gathered from observations (Part $\emptyset$)
  & use gauge invariance as the construction principle

* follow QED from $U(1)$

  ① free theory of electrons $\mathcal{L}_{\text{fermion}}(\psi, \partial_\mu \psi)$ $\rightarrow$ has a global $U(1)$ symmetry

  ② promote to a local (gauge) symmetry

  $\Rightarrow$ minimal substitution $\partial_\mu \longmapsto D_\mu = \partial_\mu + ieQ_f A^a_\mu$

  ③ add dynamics for photons: $\mathcal{L}_{\text{Maxwell}} = -\frac{1}{4} F_{\mu\nu} F^{\mu\nu}$

  (field strength tensor $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A^\mu$)

  $\Rightarrow$ $\mathcal{L}_{QED} = \mathcal{L}_{\text{fermion}}(\psi, D_\mu \psi) + \mathcal{L}_{\text{Maxwell}}$

* Let us follow the same steps to arrive at $\mathcal{L}_{QCD}$

The QCD Lagrangian

① * quarks are spin-$\frac{1}{2}$ fermions & exist in 6 "flavours" $(q = u, d, s, c, b, t)$ $\Rightarrow \psi_q$

* quarks have an additional colour d.o.f $\Rightarrow \psi_q = (\psi_q^r, \psi_q^g, \psi_q^b)^T$

↪ Dirac Lagrangian $\mathcal{L}_q(\psi_q, \partial_\mu \psi_q) = \sum_q \bar{\psi}_q^i (i\not{\partial} - m_q)\delta^{ij}\psi_q^j = \sum_q \bar{\psi}_q (i\not{\partial} - m_q)\psi_q$

* This Lagrangian has a global SU(3) symmetry $\psi_q^i \longmapsto U_{ij}\psi_q^j$

$U = \exp[-i g_s \theta^a t^a]$; $U \in SU(3)$ $(N_c^2 - 1) = 8$ parameters (θ^a) / generators (t^a)

* one explicit representation: $t^a = \lambda^a/2$ (λ^a : Gell-Mann matrices)

$$\lambda^1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda^2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda^3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad \lambda^4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}$$

$$\lambda^5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix} \quad \lambda^6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \quad \lambda^7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix} \quad \lambda^8 = \frac{1}{\sqrt{3}}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}$$

normalization

$\mathrm{tr}[t^a t^b] = T_R\,\delta^{ab}$

$T_R = \frac{1}{2}$

The QCD Lagrangian

② * $SU(N_c)$ is an exact symmetry $\rightsquigarrow$ "gauge" it $\quad (\theta^a \longmapsto \theta^a(x))$

$\Rightarrow$ For $\mathcal{L}_q$ to remain invariant, need to substitute

$$\partial_\mu \longmapsto D_\mu = \partial_\mu + i g_s \underbrace{A_\mu^a t^a}_{\mathcal{A}_\mu} \qquad \text{"covariant derivative"}$$

$\mathcal{A}_\mu$ transforms as $\mathcal{A}_\mu \mapsto U \mathcal{A}_\mu U^\dagger + \frac{i}{g_s} (\partial_\mu U) U^\dagger$

* forced us to introduce 8 new spin-1 fields, the gluons: $A_\mu^a \quad (a = 1, \dots, 8)$

③ * add dynamics for the gluon fields:

structure constant $[t^a, t^b] = i f^{abc} t^c$

$$\mathcal{L}_A = -\frac{1}{4} F_{\mu\nu}^a F^{a,\mu\nu} \qquad \text{with} \qquad F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a \underbrace{- g_s f^{abc} A_\mu^b A_\nu^c}_{\text{not present in QED}}$$

* gluon self-interaction
* no mass term allowed (not gauge invariant)

The QCD Lagrangian

* Putting it together $\left(D_\mu = \partial_\mu + i g_s A_\mu^a t^a \,,\; F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - g_s f^{abc} A_\mu^b A_\nu^c \right)$

$$\mathcal{L}_{QCD} = \sum_q \bar{\psi}_q \left(i \not{D} - m_q \right) \psi_q - \frac{1}{4} F_{\mu\nu}^a F^{a,\mu\nu}$$ fully gauge invariant by construction

* gauge symmetry introduces redundancy $\rightsquigarrow$ $\mathcal{L}_{fix}$ for reduction to physical d.o.f.

$\left[A_{\mu=0,1,2,3} \; (4) \text{ v.s. } \text{massless spin-1} \; (2) \right]$

  ↳ covariant gauge $\mathcal{L}_{fix} = -\frac{1}{2\xi} \left(\partial^\mu A_\mu^a \right)^2$

  ⇒ introduces new ghost fields to cancel unphysical d.o.f.

  * $\xi = 1$: Feynman gauge

  ↳ axial gauges $\mathcal{L}_{fix} = -\frac{1}{2\xi} \left(n^\mu A_\mu^a \right)^2$ (n^μ arbitrary $\leftrightarrow$ not covariant)

  * $n^2 = \emptyset$: "light-cone" gauge
  * $\xi \to \emptyset$: "axial" gauge is ghost free ⇒ physical modes only

Quantization & Perturbation Theory

* Quantization in the path-integral formalism:

$$\mathcal{M}_{\Phi_1 \cdots \Phi_n} \longleftrightarrow \int \mathcal{D}[\Phi]\, \Phi_1(x_1) \cdots \Phi_n(x_n)\, e^{i \int d^4x\, \mathcal{L}_{QCD}(\Phi, \partial_\mu \Phi)}$$

$\hookrightarrow \Phi \in \{\psi_q, A_\mu^a\}$

all information contained

$\Leftrightarrow$ In principle, could compute anything from it
but extremely difficult to solve (starting point for lattice QCD)

* solve approximately using perturbation theory $\alpha_s^n \leftrightarrow$ systematically improvable

$\Rightarrow$ diagrammatic representation in form of Feynman diagrams

① terms in $\mathcal{L}_{QCD}$ with $\leq 2\,\Phi$: free theory $\rightsquigarrow$ external states & propagators

② terms in $\mathcal{L}_{QCD}$ with $> 2\,\Phi$: interactions $\rightsquigarrow$ vertices

Feynman Rules of QCD

* external legs

incoming

ψ_q^i  $u^i(p)$

$\bar{\psi}_q^i$  $\bar{v}^i(p)$

A_μ^a  $\varepsilon_\mu^a(p)$

outgoing

 $\bar{\psi}_q^i$ $\bar{u}^i(p)$

 ψ_q^i $v^i(p)$

 A_μ^a $\varepsilon_\mu^a(p)^*$

* propagators

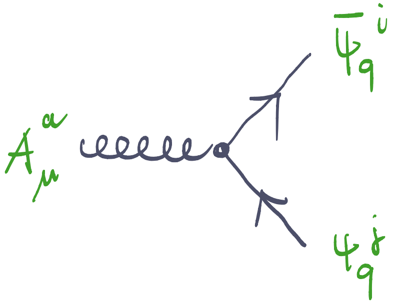
$\bar{\psi}_q^i$  ψ_q^j $\dfrac{i\delta^{ij}(\not{p}+m_q)}{p^2-m^2}$

A_μ^a  A_ν^b $\dfrac{-i\delta^{ab}}{p^2}\left[g_{\mu\nu}-(1-\xi)\dfrac{p_\mu p_\nu}{p^2}\right]$ covariant gauge

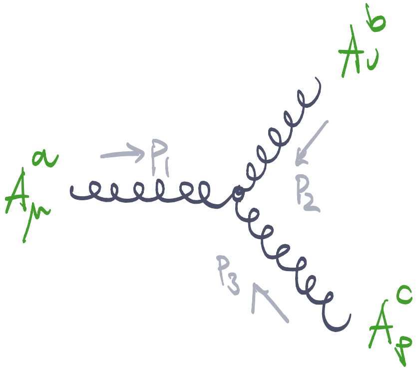
$\bar{u}^a$  u^b $\dfrac{i\delta^{ab}}{p^2}$ (the Fadeev-Popov ghost)

Feynman Rules of QCD

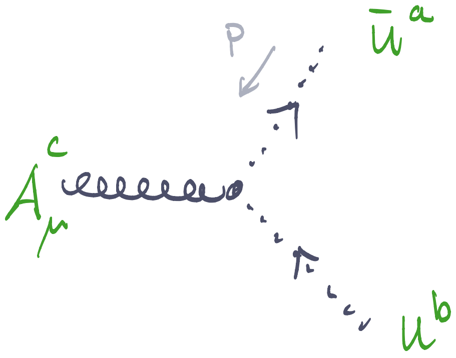
* Vertices



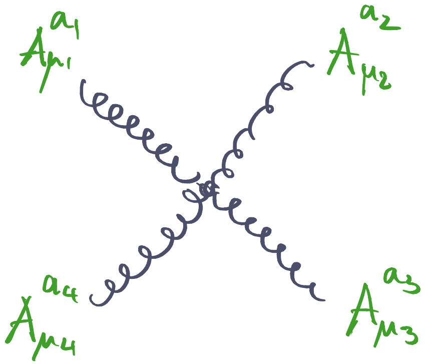
$$-i g_s (t^a)_{ij} \gamma_\mu$$



$$-g_s f^{abc}\left[g_{\mu\nu}(p_1-p_2)_\rho + g_{\nu\rho}(p_2-p_3)_\mu + g_{\rho\mu}(p_3-p_1)_\nu\right]$$



$$g_s f^{abc} p_\mu$$

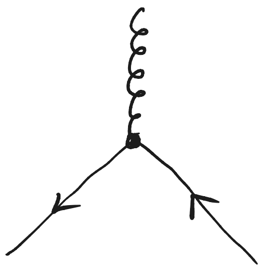


$$-i g_s^2 \left[f^{a_1a_2b} f^{a_3a_4b}\left(g^{\mu_1\mu_3}g^{\mu_2\mu_4} - g^{\mu_1\mu_4}g^{\mu_2\mu_3}\right) + \text{perms}\right]$$

Colour Algebra

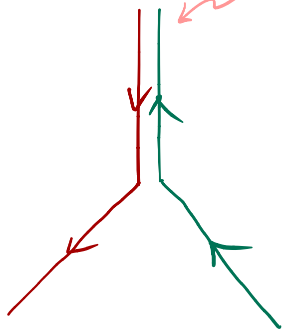
* main distinction from QED: colour $\longleftrightarrow$ non-Abelian group ($U_1U_2 \neq U_2U_1$)

* pictorial representation of quark-gluon interaction



$\bar{\psi}^i \quad t^a_{ij} \quad \psi^j$

$$\underbrace{(1,0,0)}_{\bar{\psi}^r}\underbrace{\begin{pmatrix}0&1&0\\1&0&0\\0&0&0\end{pmatrix}}_{t^1}\underbrace{\begin{pmatrix}0\\1\\0\end{pmatrix}}_{\psi^g} \quad \longleftrightarrow$$



gluons carry colour & anti-colour

↪ "repaint" the quarks

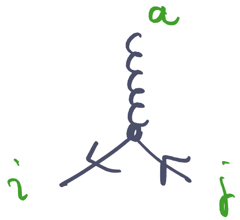
Graphical Representation of $SU(N_c)$

* propagators $\longleftrightarrow$ identity matrix

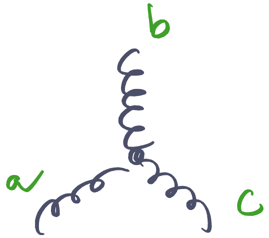
δ^{ij}

δ^{ab}

* vertices $\longleftrightarrow$ generators

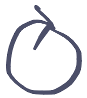


$(t^a)_{ij}$



$i f^{abc}$ ← ordering matters

* loops $\longleftrightarrow$ traces



$\mathrm{Tr}[\mathbb{1}_F] = \delta^{ii} = N_c$

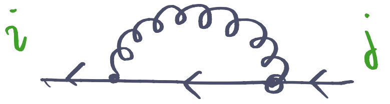
$\mathrm{Tr}[\mathbb{1}_A] = \delta^{aa} = N_c^2 - 1$

$\mathrm{Tr}[t^a] = \phi$

$\mathrm{Tr}[T^a_{(ad)}] = \phi$ (f^{abc} anti-symm.)

Graphical Representation of $SU(N_c)$

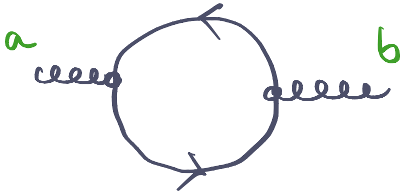
* normalization & quadratic Casimirs



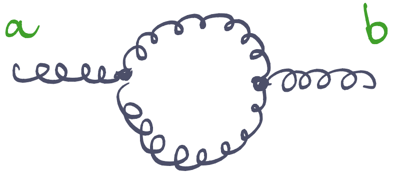
$$= \sum_a t^a t^a = C_F\, \delta^{ij} = C_F$$ 

$$C_F = T_R \frac{N_c^2 - 1}{N_c} = \frac{4}{3}$$

show this as an exercise



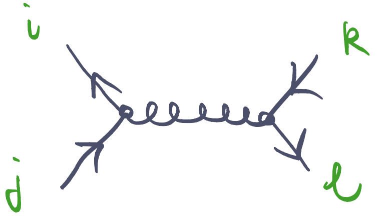
$$= \mathrm{Tr}[t^a t^b] = T_R\, \delta^{ab} = T_R$$ 



$$= \sum_c T^c_{(ad)} T^c_{(ad)} = C_A\, \delta^{ab} = C_A$$ 

$$C_A = 2\, T_R\, N_c = 3$$

* Fierz identity



$$= T_R \Big[$$  $$- \frac{1}{N_c}$$  $$\Big]$$

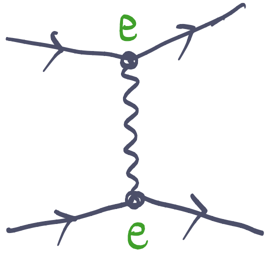
Renormalization & the Running Coupling

* all parameters, i.e. also α_s, must be determined experimentally
  ⟹ renormalization: measurable quantities expressed in terms of measurable quantities

* QED ⟶ the fine structure constant $\alpha = \frac{e^2}{4\pi}$

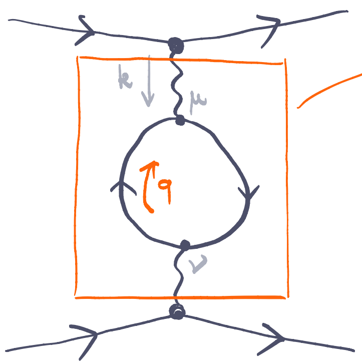
EM interaction ⟷ exchange of photon

Let's imagine, we measure it from the scattering of 2 charged particles



$\mathcal{M}^{(0)} \sim \alpha$

exchange affected by vacuum polarization (higher order corr.)



$\mathcal{M}^{(1)} \sim \alpha^2$

$$\int \frac{d^4q}{(2\pi)^4} \frac{\mathrm{Tr}\left[\gamma^\mu (\not{q}+m)\gamma^\nu(\not{q}+\not{k}+m)\right]}{(q^2-m^2)\left[(q+k)^2-m^2\right]}$$

$$\underset{q \text{ large}}{\sim} \int dq \; q^3 \frac{\{1, q, q^2\}}{q^4}$$

at least $\int \frac{dq}{q}$ in the UV

logarithmic divergent ?!

Intermezzo: Dimensional Regularization

* modify theory $\left(\text{e.g. } \int_0^\infty d^4q \to \int_{|q|<\Lambda} d^4q \right)$ to render expression finite w/ parameter (Λ)
  - ↪ original (divergent) expression by taking limit of parameter $(\Lambda \mapsto \infty)$
* de facto standard: dimensional regularization using $D = 4 - 2\epsilon$ as dimension
  - ↪ preserves Lorentz- & gauge-invariance; works also for the infrared
  - ↪ divergence as poles in $\frac{1}{\epsilon^n}$ $(\epsilon \to 0)$
  - ↪ momentum integrals: $\int \frac{d^4q}{(2\pi)^4} \to \int \frac{d^Dq}{(2\pi)^D}$ (impose integral axioms)
  - ↪ retain dimensionless coupling $g \to \mu^{\frac{4-D}{2}} g = \mu^{\epsilon} g$ why this power?

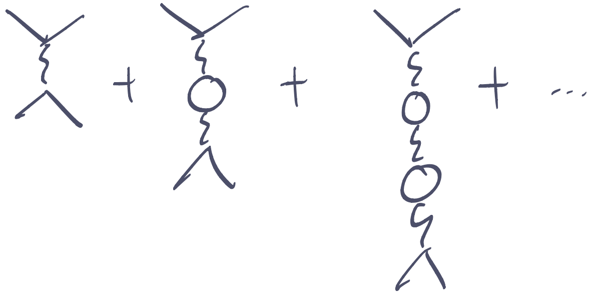
need to introduce a scale

Renormalization & the Running Coupling

* with DimReg, we obtain the ~~following~~ result

 $= \left[-\Pi^{\gamma\gamma}(k^2)\right] \cdot$ 
with $\quad \Pi^{\gamma\gamma}(k^2) = \frac{\alpha}{3\pi}\left[\frac{1}{\epsilon} - \gamma_E + \ln(4\pi) + \ln\left(\frac{\mu^2}{k^2}\right) + \frac{5}{3}\right] + \mathcal{O}(\epsilon)$

* we can anticipate even more bubble insertions:



$$= \mathcal{M}^{(0)}\left[1 + \left[-\Pi^{\gamma\gamma}\right] + \left[-\Pi^{\gamma\gamma}\right]^2 + \ldots\right]$$

$$= \mathcal{M}^{(0)} \sum_{n=0}^{\infty}\left[-\Pi^{\gamma\gamma}\right]^n = \mathcal{M}^{(0)} \frac{1}{1+\Pi^{\gamma\gamma}}$$

Dyson sum

Renormalization & the Running Coupling

* Let's make the coupling dependence explicit and label it the bare coupling α^{bare} in anticipation of the renormalization step.

$$\mathcal{M}^{(0)} = \alpha^{\text{bare}}\,\bar{\mathcal{M}}^{(0)}, \qquad \Pi^{\gamma\gamma}(k^2) = \alpha^{\text{bare}}\,\bar{\Pi}^{\gamma\gamma}(k^2)$$

↪ we can introduce an effective coupling $\alpha^{\text{eff}}(k^2)$ that incorporates all bubble insertions

$$\mathcal{M}^{\Sigma} = \bar{\mathcal{M}}^{(0)} \underbrace{\frac{\alpha^{\text{bare}}}{1+\alpha^{\text{bare}}\,\bar{\Pi}^{\gamma\gamma}(k^2)}}_{\equiv\, \alpha^{\text{eff}}(k^2)} = \mathcal{M}^{(0)}\Big|_{\alpha^{\text{bare}} \to \alpha^{\text{eff}}(k^2)}$$

Renormalization & the Running Coupling

* Now, in the final step, we will renormalize the coupling.

$\Leftrightarrow$ we perform a measurement of α $\leftrightsquigarrow$ defines the renormalization scheme

* e.g. let's define α as measured at the Z pole

$$\alpha^{ren} \equiv \alpha^{eff}(Q^2 = M_Z^2) = \frac{\alpha^{bare}}{1 + \alpha^{bare}\, \underbrace{\overline{\Pi}^{\gamma\gamma}(M_Z^2)}} \simeq 1/129$$

what if we had picked the Thompson limit? ($Q^2 \to \emptyset$)

this is a finite measured value!

this has divergences!

* We can rewrite all $\alpha_s^{eff}(Q^2)$ in terms of the measured value α^{ren}

$$\frac{1}{\alpha^{eff}(Q^2)} = \frac{1}{\alpha_{ren}} \left[\overline{\Pi}^{\gamma\gamma}(Q^2) - \overline{\Pi}^{\gamma\gamma}(M_Z^2)\right]$$

something magical has happened!

Renormalization & the Running Coupling

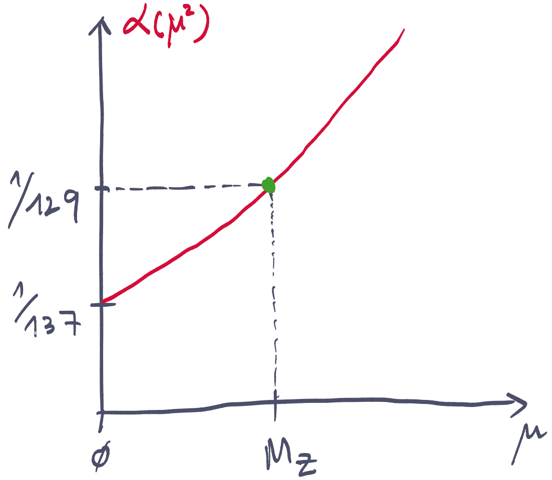
* by expressing measurable quantities $\alpha^{eff}(Q^2)$ in terms of measured quantities α^{ren}

$\Leftrightarrow$ all divergences have disappeared Renormalization

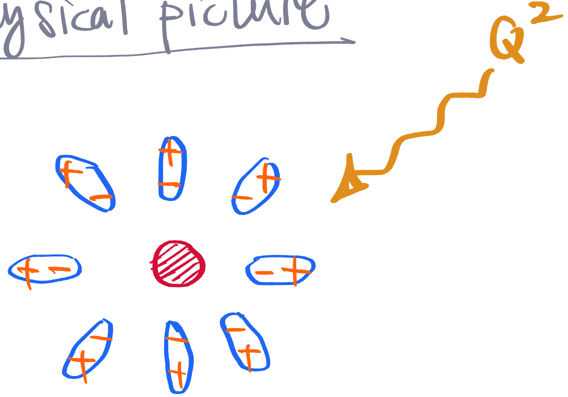
$$\Big[\underbrace{\Pi^{\gamma\gamma}(Q^2)}_{\cancel{\frac{1}{\epsilon}}} - \underbrace{\Pi^{\gamma\gamma}(M_Z^2)}_{\cancel{\frac{1}{\epsilon}}}\Big] = \frac{1}{3\pi}\left[\ln\left(\mu^2/Q^2\right) - \ln\left(\mu^2/M_Z^2\right)\right] = -\frac{1}{3\pi}\ln\left(Q^2/M_Z^2\right)$$

* what we get is the running QED coupling

$$\alpha(\mu^2) = \frac{\alpha(\mu_0^2)}{1 - \frac{\alpha(\mu_0^2)}{3\pi}\ln\left(\mu^2/\mu_0^2\right)}$$



physical picture



Q^2 small $\longleftrightarrow$ large λ : screening

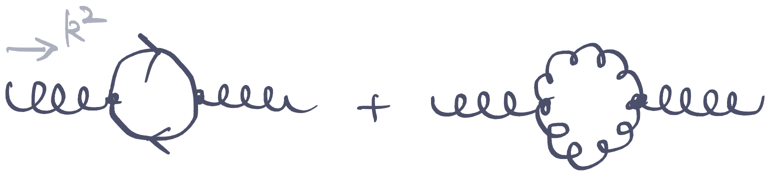
Q^2 large $\longleftrightarrow$ small λ : "see" more of $\ominus$

Renormalization & the Running Coupling

* QCD: more subtle because gluons carry colour & gauge cancellations

  ⟷ exploit gauge freedom: light-cone (axial) gauge ⇝ only 

* now we have two diagrams



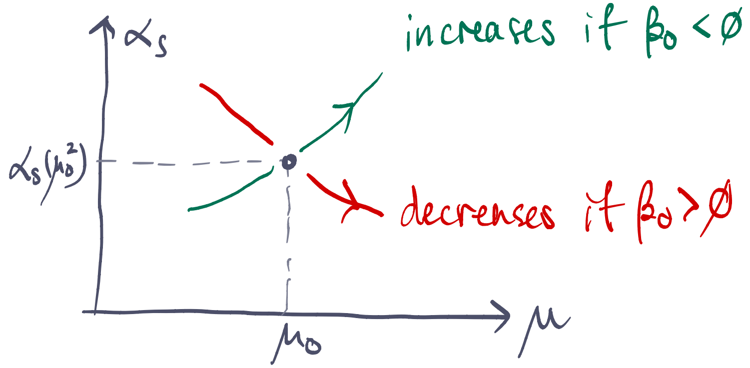
$$= \Pi^{gg}(k^2) = -\frac{\alpha_s^{\text{bare}}}{2\pi}\left[\beta_0\left(\frac{1}{\epsilon}-\gamma_E+\ln(4\pi)+\ln\left(\mu^2/k^2\right)\right)+h+\mathcal{O}(\epsilon)\right]$$

constant (no k^2-dep)

with $\beta_0 = \frac{11}{6}C_A - \frac{N_f}{3}$ ← # flavours

* following same steps as in QED: running of $\alpha_s(\mu^2)$ (at lowest order)

$$\alpha_s(\mu^2) = \frac{\alpha_s(\mu_0^2)}{1+\beta_0\,\frac{\alpha_s(\mu_0^2)}{2\pi}\,\ln\left(\mu^2/\mu_0^2\right)}$$



[for $N_f \leq 16$]

asymptotic freedom

Renormalization & the Running Coupling

* asymptotic freedom: $\alpha_s(\mu^2) \to \emptyset$ for $\mu^2 \to \infty$
  - ↪ feature of non-Abelian gauge theories
    - ⇒ at high scales: hadrons $\hat{=}$ collection of free partons & pQCD applicable
* scale choice μ is arbitrary ⇝ mass scale of QCD Λ_{QCD}

$$\Lambda_{QCD} \simeq \mu_0 \exp\left\{ -\frac{1}{2\beta_0 \frac{\alpha_s(\mu_0^2)}{2\pi}} \right\} \simeq 200\,\text{MeV}$$

← signals breakdown of perturbative treatment

$$\Rightarrow \quad \alpha_s(\mu^2) = \frac{1}{\frac{\beta_0}{2\pi} \ln\left(\mu^2/\Lambda_{QCD}^2\right)}$$

* Why does no one talk about Λ_{QED}?

Renormalization & the Running Coupling

* cross section for scale choice μ_0

$$\sigma(\alpha_s(\mu_0),\mu_0) = \left(\frac{\alpha_s(\mu_0)}{2\pi}\right)^n \underbrace{\sigma^{(0)}}_{\text{LO}} + \left(\frac{\alpha_s(\mu_0)}{2\pi}\right)^{n+1} \underbrace{\sigma^{(1)}}_{\text{NLO}} + \dots$$

scale variation @ lower orders generates higher-order terms

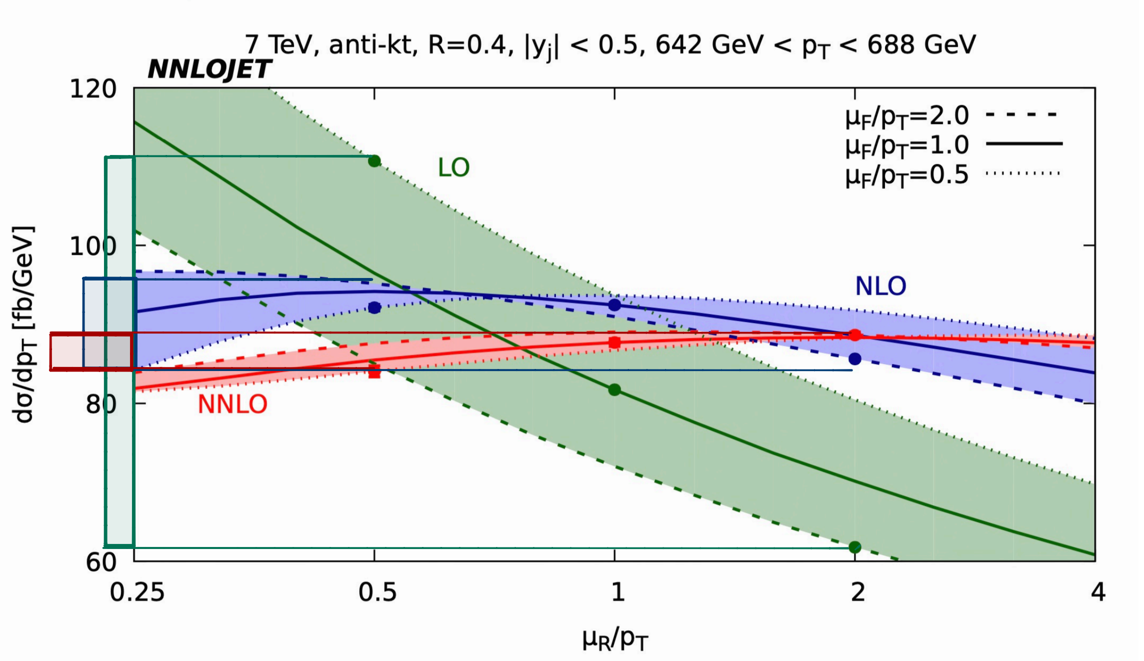
→ prediction for scale dependence

$$\sigma(\alpha_s(\mu),\mu) = \left(\frac{\alpha_s(\mu)}{2\pi}\right)^n \sigma^{(0)} + \left(\frac{\alpha_s(\mu)}{2\pi}\right)^{n+1} \left[\sigma^{(1)} + n\,\beta_0 \ln\left(\frac{\mu^2}{\mu_0^2}\right)\sigma^{(0)}\right] + \dots$$

⇒ handle on missing terms from truncation of the perturbative series

"scale uncertainties"

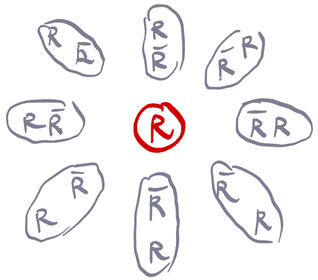
(no statistical meaning!)



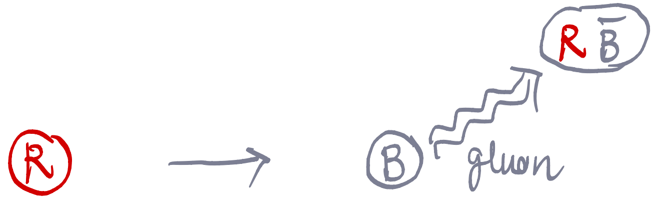
Renormalization & the Running Coupling

physical picture:

① screening

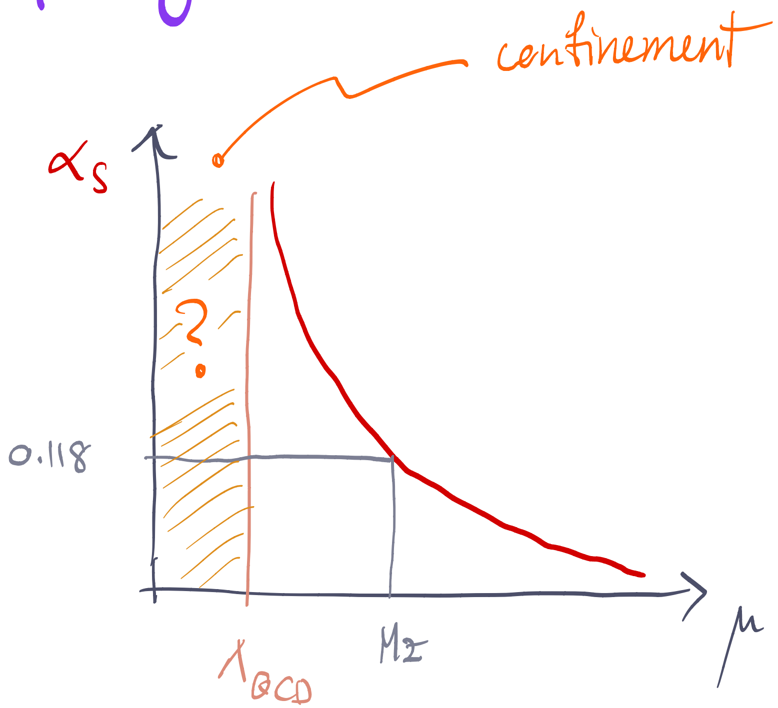


② anti-screening



net charge: still R
but gluon spreads
the charge

↳ the closer I look (high Q^2 → small λ)
→ chance of finding R → ∅
(this effect dominates over the screening)



Renormalization & the Running Coupling

* more formally:

$$\alpha_s^{bare} = \mu^{2\epsilon} Z_{\alpha_s} \alpha_s^{ren} \quad \& \quad \frac{d\alpha_s^{bare}}{d\mu} \stackrel{!}{=} 0$$

$\Rightarrow$ beta function

$$\beta(\alpha_s) = \frac{1}{\alpha_s} \frac{d\alpha_s}{d\ln\mu^2} = -\sum_{n=1}^{\infty} \beta_{n-1} \left(\frac{\alpha_s}{2\pi}\right)^n$$

* known to 5 loops

$$\beta_0 = 11 - \frac{2}{3} n_f , \qquad \beta_1 = 102 - \frac{38}{3} n_f ,$$

$$\beta_2 = \frac{2857}{2} - \frac{5033}{18} n_f + \frac{325}{54} n_f^2 ,$$

$$\beta_3 = \frac{149753}{6} + 3564\zeta_3 + n_f\left(-\frac{1078361}{162} - \frac{6508}{27}\zeta_3\right) + n_f^2\left(\frac{50065}{162} + \frac{6472}{81}\zeta_3\right) + \frac{1093}{729} n_f^3$$

$$\beta_4 = \frac{8157455}{16} + \frac{621885}{2}\zeta_3 - \frac{88209}{2}\zeta_4 - 288090\zeta_5 + n_f\left(-\frac{336460813}{1944} - \frac{4811164}{81}\zeta_3 + \frac{33935}{6}\zeta_4 + \frac{1358995}{27}\zeta_5\right) + n_f^2\left(\frac{25960913}{1944} + \frac{698531}{81}\zeta_3 - \frac{10526}{9}\zeta_4 - \frac{381760}{81}\zeta_5\right) + n_f^3\left(-\frac{630559}{5832} - \frac{48722}{243}\zeta_3 + \frac{1618}{27}\zeta_4 + \frac{460}{9}\zeta_5\right) + n_f^4\left(\frac{1205}{2916} - \frac{152}{81}\zeta_3\right)$$

* running

↳ τ decay

$M_\tau \sim 2$ GeV

↳ LEP

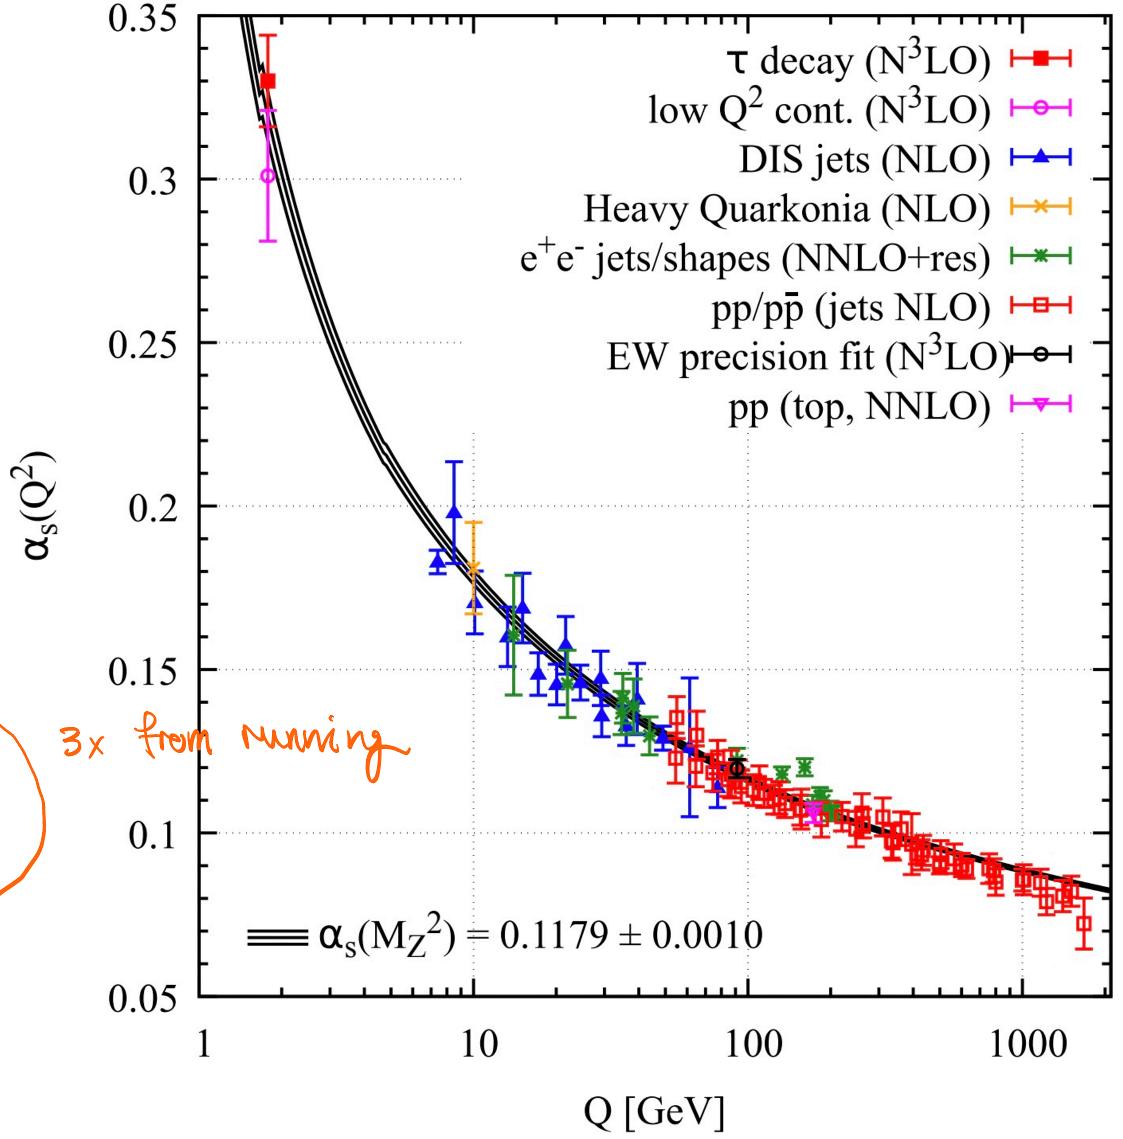
$M_Z \sim 100$ GeV

3x from running

↳ LHC

$Q \sim 1$ TeV

$$\alpha_s(M_Z^2) = 0.1179 \pm 0.0010 .$$



Determinations of α_s

* τ decays & low Q^2 $\longrightarrow$ running helps!

$\alpha_s(M_Z^2) = 0.1173\,(17)$ $\qquad$ $(\alpha_s(m_\tau^2) = 0.314\,(14))$

$\delta' = [\alpha_s(M_Z^2)/\alpha_s(Q^2)]^2\,\delta$

* quarkonia decays $\longrightarrow$ α_s sensitivity $\Gamma(\Upsilon \to \mathrm{had}) \sim \alpha_s^3$

$\alpha_s(M_Z^2) = 0.1181\,(37)$

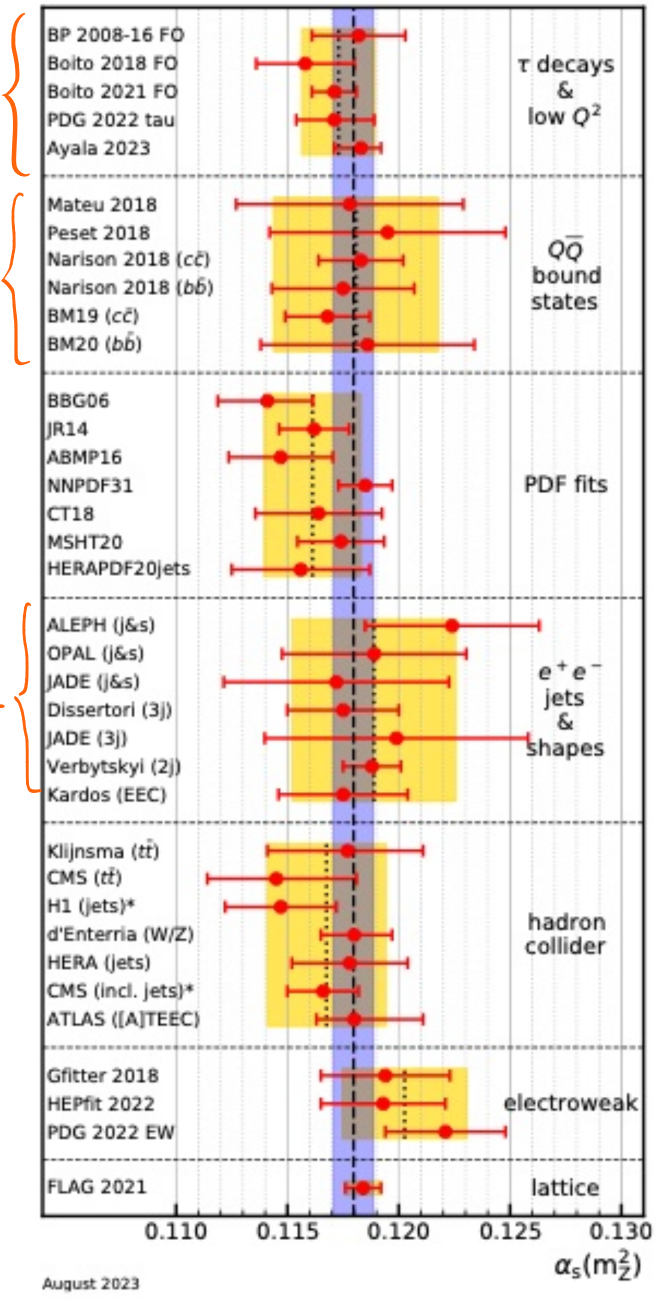
* hadronic final states in e^+e^-

↳ $e^+e^- \to$ hadrons $\longrightarrow$ weak α_s sensitivity but NP $\sim (\Lambda_{QCD}/Q)^4$

↳ event shapes $\longrightarrow$ LO α_s sensitivity but NP $\sim (\Lambda_{QCD}/Q)$

$\alpha_s(M_Z^2) = 0.1189\,(37)$

* World average $\quad \alpha_s(M_Z^2) = 0.1180\,(9)$

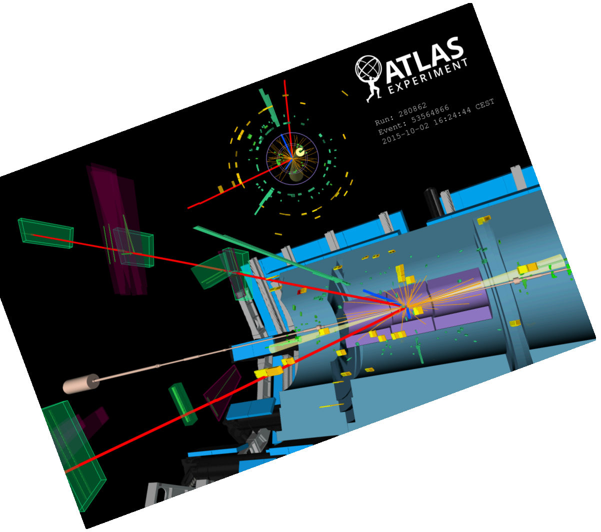


Recap

* QCD: non-Abelian gauge theory with spin-½ matter quark fields
  - ↳ describes the pattern of hadrons we observe (mesons: $q\bar{q}$, baryons qqq)
  - ↳ analogous construction as QED
* non-Abelian group $SU(N_c)$ ⇝ gluons also carry colour (self interactions)
  - ↳ much more complex algebra
  - ↳ diagrammatic representation, e.g.  $= C_F \rightarrow$
* renormalization & asymptotic freedom
  - ↳ UV divergences inside loops → requires regularization: DimReg $D = 4 - 2\epsilon$
  - ↳ renormalization → measurable quantities in terms of measured parameters
    ⇒ all UV divergences cancel!
  - ↳ the running coupling $\alpha_s(\mu^2)$

Extra

From Lagrangian Densities to Event Rates



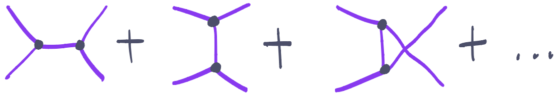
Event Rates

$$\underbrace{N = L\,\sigma}$$

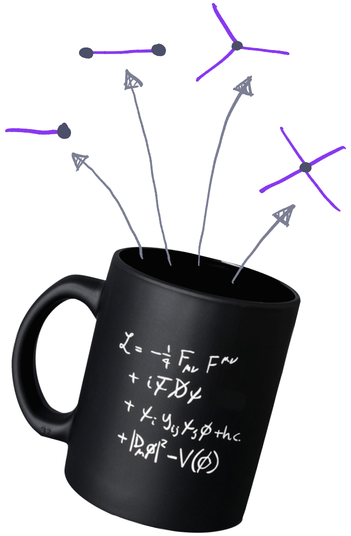
↳ **Cross Sections**

$$d\sigma_{2\to n} = \frac{1}{F}\underbrace{\langle|\mathcal{M}|^2\rangle}\, d\Phi_n$$

↳ **Scattering Amplitudes**



Feynman diagrams & rules ⟷ $\mathcal{L}$

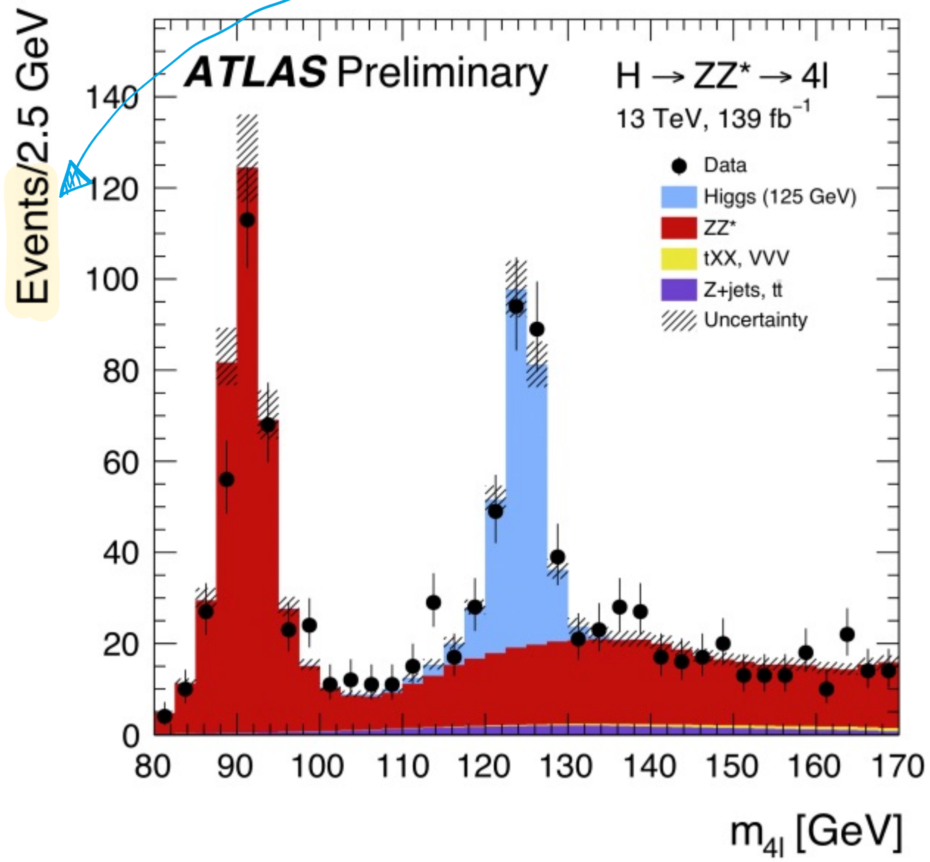


* another important case Decay Rates ($\tau = 1/\Gamma$)

$$d\Gamma_{1\to n} = \frac{1}{2M}\langle|\mathcal{M}|^2\rangle\, d\Phi_n$$

Event Rates

We ultimately measure # Events
for a specific process: $a + b \to 1 + 2 + \ldots + n$



Luminosity ~ # collisions

cross section

$$dN = L \, d\sigma$$

$*$ σ_H (13 TeV) ≈ 50 pb

$\int_{Run2} dt \, \mathcal{L} \approx 150 \text{ fb}^{-1}$

~ 7 million Higgs bosons produced!

$*$ σ_Z (13 TeV) $\simeq 50$ nb

$\sigma_{W^\pm}$ (13 TeV) $\simeq 200$ nb

$\mathcal{L}$ (instantaneous) $\simeq 0.02 \text{ pb}^{-1} \text{s}^{-1}$

~ 1000 Z's
~ 4000 $W^\pm$'s
every second!

Calculating Cross Sections

Fermi's Golden Rule $\quad a+b \to 1+2+\dots+n$

$$d\sigma = \underbrace{\frac{1}{F}}_{\text{flux}} \; \underbrace{\langle |\mathcal{M}|^2 \rangle}_{|\text{amplitude}|^2} \; \underbrace{d\Phi}_{\substack{\text{phase space}\\ \text{(LIPS)}}}$$

$$= \frac{1}{4(p_a \cdot p_b)} = \frac{1}{2E_{cm}^2}$$

$$= \frac{1}{n_a^{d.o.f.}\, n_b^{d.o.f.}} \sum_{d.o.f.} |\mathcal{M}|^2$$

(degrees of freedom
spin, colour)

$$d\Phi_n(p_1,\dots,p_n;\, p_a+p_b) = \prod_{i=1}^{n} \frac{d^4 p_i}{(2\pi)^4} (2\pi)\,\delta(p_i^2 - m_i^2)\, \Theta(p_i^0)$$

"on shell"

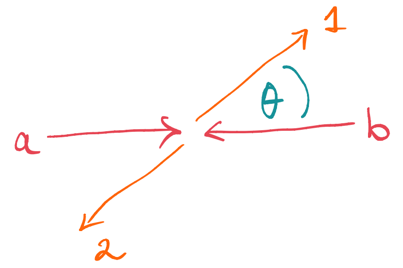
$E_i > 0$

$$(2\pi)^4\, \delta^{(4)}(p_1 + \dots + p_n - (p_a + p_b))$$

energy-momentum conservation

Special case $\quad a+b \to 1+2$

$$d\Phi_2 = \frac{d\cos\theta}{16\pi} \quad \text{(massless)}$$



Exercise: Lepton Collider

Consider the process $e^+ e^- \to \mu^+ \mu^-$

at lowest order (tree level). There are two diagrams

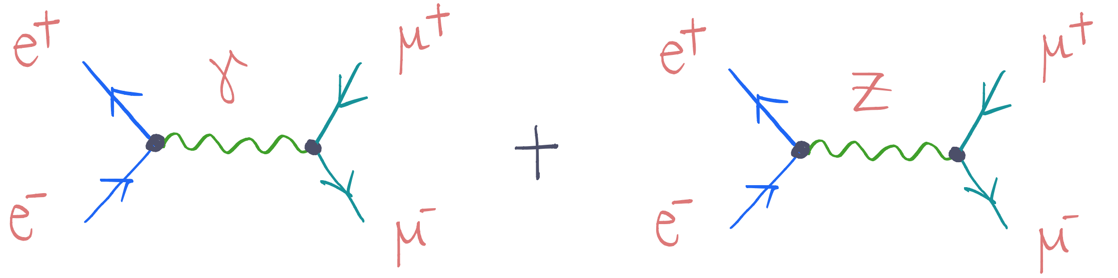
What are they? [demo: FeynGame]

Exercise: Lepton Collider

[demo: $e^+e^- \to \mu^+\mu^-$]

Consider the process $e^+ e^- \to \mu^+ \mu^-$

at lowest order (tree level). There are two diagrams



$= i\mathcal{M}^{\text{tree}}_{e^+e^-\to\mu^+\mu^-}$

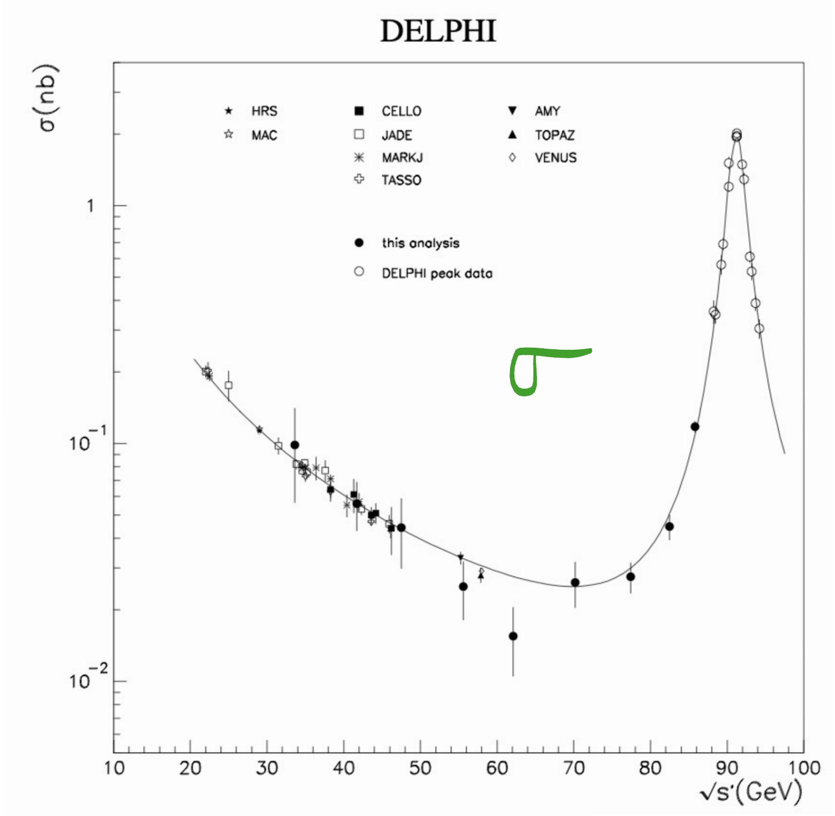
$\Rightarrow$ Inserting into Fermi's golden rule $[\,s = E_{CM}^2\ ;\ p_a \cdot p_1 = p_a^\mu\, p_{1,\mu} = E_{cm}^2 (1-\cos\theta)\,]$

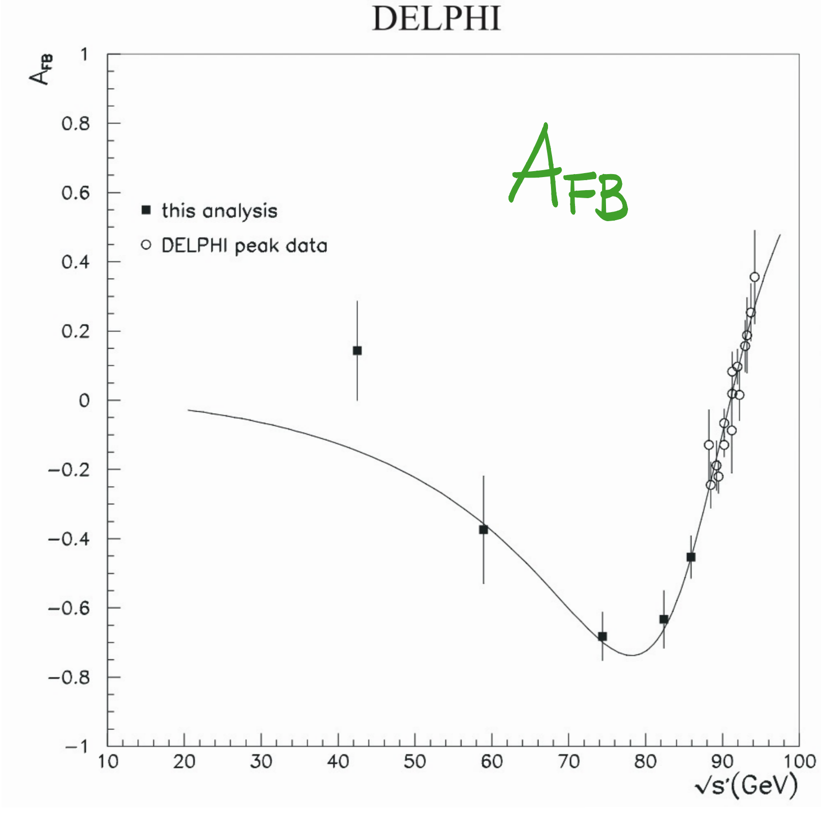
$$\frac{d\sigma}{d\cos\theta} = \frac{\alpha^2 \pi}{2s}\left[(1+\cos^2\theta)\, G_1(s) + 2\cos\theta\, G_2(s)\right]$$

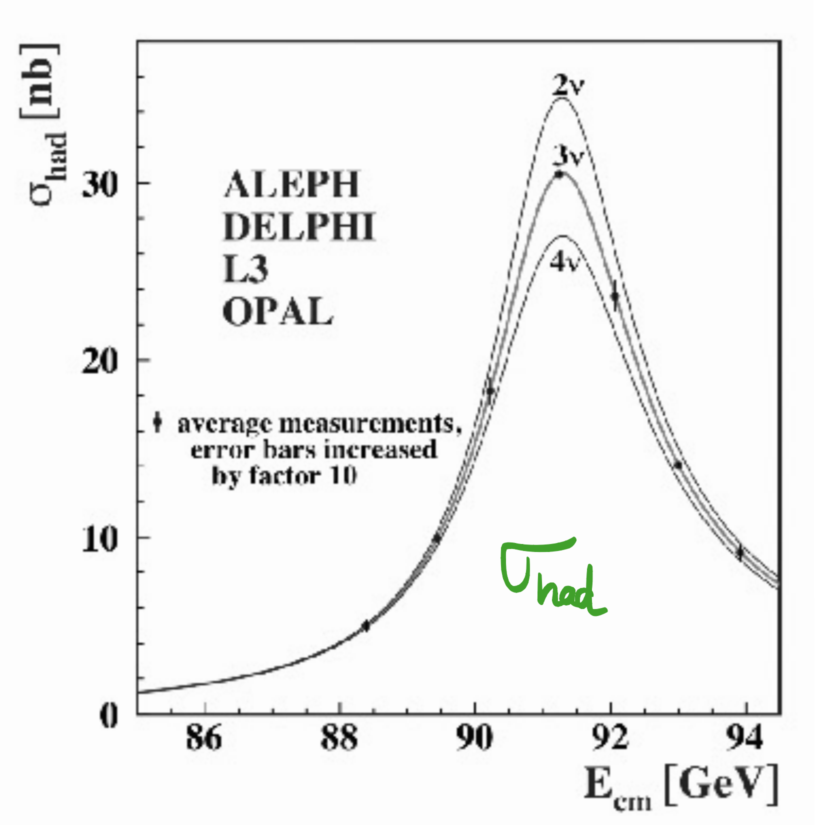
$$G_1(s) = 1 + 2v_\ell^2\, \mathrm{Re}\left\{\frac{s}{s-M_Z^2+iM_Z\Gamma_Z}\right\} + (v_\ell^2+a_\ell^2)\left|\frac{s}{s-M_Z^2+iM_Z\Gamma_Z}\right|^2$$

$$G_2(s) = 0 + 2a_\ell^2\, \mathrm{Re}\left\{\frac{s}{s-M_Z^2+iM_Z\Gamma_Z}\right\} + 4v_\ell^2 \cdot a_\ell^2\left|\frac{s}{s-M_Z^2+iM_Z\Gamma_Z}\right|^2$$

"Comparison" to Data







* In principle, you now can use the predictions to fit M_Z & $\sin^2\theta_W$ from the data (at leading order)
* σ_{had} is the hadronic cross section: @ LO: $e^+e^- \to q\bar{q}$
  $\Rightarrow$ what changes compared to $\mu^+\mu^-$?
